# What Field Audit does, screen by screen

Field Audit is the tablet app a warehouse inspector carries during a cycle count. It turns a paper clipboard exercise — walk the rack, check what's on it against what should be there, flag what's wrong — into a guided flow: pick a location, scan the SKU, reconcile it, move to the next. This handbook walks through every screen and the handful of journeys an inspector actually runs end to end.

|                       |                                |                     |
|-----------------------|--------------------------------|---------------------|
| Platform              | Core loop                      | Primary user        |
| iPad / Android tablet | Scan → Reconcile → Save & Next | Warehouse inspector |

Screen – Login

## Login

The inspector's entry point. Confirms who's counting and which warehouse they're assigned to before anything else loads.

- **Warehouse chip** — shows which site this device is provisioned for.
- **Email / password** — standard credentials; errors surface inline, not as a popup.
- A failed attempt never wipes what was typed — only the password field clears.

# Dashboard

The first thing an inspector sees after logging in: what's already in progress, and how far through the week they are.

- **Ongoing Audit banner** — the one audit currently mid-count. Its button is the fastest way back into work: **Resume Audit** or, once every location is counted, **View Audit Summary**.
- **Audit Overview** — a single completion percentage across every assigned audit.
- **Ongoing Audit detail** — warehouse, rack, bay counts, and how many locations are still pending.

# Tasks

Every assigned audit sorted by how soon it's due — the inspector's worklist for the week.

- Four fixed columns: **Delayed, Today, This Week, This Month.**
- A completed or closed audit drops off the board entirely — nothing to action, nothing shown.
- **View Tasks on 3D** jumps to the Warehouse Map for a spatial view of the same list.

## Warehouse Map

The same task list as a floor plan — useful when the question is "what's physically closest to me right now," not "what's due soonest."

- Every layout drawn as a row of racks, each rack as its own stack of bays — not a simplified block.
- Colour reads task state at a glance: **overdue**, **completed**, **assigned**.
- Tapping a rack or bay opens its task list; **Start Task** routes straight into Rack View.

# Audit Schedule

A calendar view of every audit by its scheduled date — for planning ahead rather than working the day's list.

- Month, week, and day views of the same underlying schedule.
- Colour-coded by audit type: Spot Check, Full, Cycle Count.
- Tapping a day opens that date's audits grouped by type.

# Audit Details

The audit's briefing page — what it covers and how much of it is actually done — before the inspector commits to starting or resuming it.

- **Inspection Schedule** card: type, date, and priority.
- **Bay chip grid** shows every bay in scope, green once completed. Scope spanning more than one rack collapses into a Layout → Rack → Bays accordion instead of one long grid.
- A Zone-scoped audit shows zone chips here instead of bay chips — there's no rack structure to drill into.

# Rack View – the canvas

Where the actual counting happens. A schematic elevation of the whole rack — every bay, every level, every slot — so the inspector can see exactly where they are before touching a pallet.

- All bays in the rack render side by side, not one at a time.
- The **Scan Direction** toolbar (bottom) sets the walking order: which side to start from, and whether each new level restarts from that side or snakes from wherever the last one ended.
- A small number on each slot shows exactly where it falls in that order — tap From/Pattern and watch the numbers re-flow.
- **Scope** (top-right of the canvas) decides how far that order reaches: **Bay 's Level1** stays inside the current bay; **Bay wise** sweeps the whole rack, one level at a time.

## Reconciliation Form

Selecting a slot opens this panel beside the canvas — not over it — so the inspector never loses their place on the rack while filling it in.

- Scanning is its own step: a dotted target, tapped deliberately, not automatic on selection.
- A scanned SKU compares instantly against what's expected: **Matched** or **Mismatch**.
- **Quantity** and **Damage** are logged independently — a pallet can be wrong on one, both, or neither, and each gets its own Raise Issue and evidence (note, photo, audio).
- **Save & Scan Next** commits the record and jumps straight to the next pending slot in the active Scan Direction order — no manual re-navigation.

# Manual Mode

For the pallet that's wrong but was never part of this audit's plan — found damaged three bays over from where the inspector is actually assigned.

- Flipping the toggle opens every pallet in the physical rack for selection, not just the ones in scope — those extra slots get a dashed amber border on the canvas.
- The form drops the Expected/Scanned comparison — there's nothing on file to compare against — and becomes a straightforward **Manual Issue Report**.
- **Raise Issue** both saves the report and advances to the next slot, same as normal mode.

# Quick Scan

For finding one specific pallet fast, outside the normal walk-the-rack flow — three modes for three different starting points.

- **Zone** — scan into a broad warehouse zone when there's no rack structure to speak of.
- **Rack** — pick a Layout, Rack and Bay, then tap a slot on the same canvas Rack View uses.
- **Floor** — scan first, pin its exact spot on the floor plan second; the form stays locked until the pin is placed.
- Every find lands in one running list, grouped by which mode found it.

- Zone mode
- Rack mode – next screenshot
- Floor mode – next screenshot

## Screen – Reported Audits

# Reported Audits

Every flagged pallet across every assigned audit, in one board — the view a lead uses to see what actually needs following up on.

- Cards group into **Matched SKUs** (right item, wrong qty/damage) and, behind the **Mismatch SKUs** toggle, **Mismatch** plus **Manually Reported** cases.
- Badge severity is ranked, not just tagged: a wrong SKU always outranks damage, which always outranks a quantity-only issue.
- The filter picker narrows by Severity, **Type** (Reconciliation Form vs. Manual Report), Rack, Bay, or Damage — active filters show as removable chips below the toolbar.

# Five journeys an inspector actually runs

Every other flow in the app is a variation on one of these five — start here when explaining the app to someone new.

## 1. Complete a scheduled audit from scratch

Most common — the core loop

### 1 Open the task.

From **Tasks** or the **Dashboard**'s task list, tap the audit due today.

### 2 Review the brief.

**Audit Details** shows scope and bay progress. Tap **Start Audit**.

### 3 Set the walking order.

In **Rack View**, confirm or change the **Scan Direction** — From, Pattern, Scope — so the slot numbers match how you'll actually walk the aisle.

### 4 Select a slot, scan the SKU.

Tap the pallet on the canvas, then **Tap to Scan SKU** in the Reconciliation Form.

### 5 Reconcile.

Confirm quantity and condition; raise an issue if either is off. Attach a photo or note if it matters later.

### 6 Save & Scan Next.

The form advances to the next slot in the active order automatically — repeat from step 4.

### 7 Finish the audit.

Once every location is counted, the Dashboard's action button switches to **View Audit Summary**.

## 2. Resume an audit that's already in progress

Coming back mid-shift

### 1 Open the Dashboard.

The Ongoing Audit banner is already showing the in-progress audit.

---

### 2 Tap Resume Audit.

This skips Audit Details entirely.

---

### 3 Land exactly where you left off.

Rack View opens on the last-touched location, Reconciliation Form already open — no re-navigating the rack to find your place.

## 3. Report a pallet outside your assigned scope

Something's wrong, but it's not on your list

### 1 Notice the problem.

A damaged or misplaced pallet in a bay you're walking past, but not actually assigned to count.

---

### 2 Turn on Manual Mode.

In Rack View's toolbar, flip the **Manual Mode** switch — every pallet in the physical rack becomes selectable.

---

### 3 Select the pallet, scan it.

Same dotted scan target as normal mode.

---

### 4 Describe what you found.

No expected SKU to compare against, so log quantity/condition directly and attach evidence.

---

### 5 Raise Issue.

Saves the report and advances to the next slot. Reopening a reported pallet shows a collapsed summary instead of the full form.

## 4. Chase down one specific pallet

You know the SKU, not necessarily where it is

### 1 Open the Scan tab.

Bottom navigation → **Scan**.

---

### 2 Pick the mode that matches what you know.

**Zone** if you only know the general area, **Rack** if you know the rack/bay, **Floor** if it's sitting in the open.

---

### 3 Scan it.

Zone and Rack resolve the location immediately. Floor asks you to pin the spot after scanning.

---

### 4 Reconcile and save.

Same qty/condition/evidence pattern as Rack View.

---

### 5 Check the running list.

The list icon in the toolbar shows every find this session, grouped by mode.

## 5. Review what's been flagged across every audit

Usually a lead, checking in on the team's progress

### 1 Open Reported Audits.

Bottom navigation → **Reported Audits**.

---

### 2 Narrow the list.

Tap the filter icon — filter by Severity, Type (Reconciliation Form vs. Manual Report), Rack, Bay, or Damage.

---

### 3 Toggle Mismatch SKUs

to switch between "matched but off on qty/damage" and "wrong item entirely / manually reported."

---

### 4 Open a card.

Drills into that pallet's full record — evidence, expected vs. scanned, who raised it.

Screenshots are taken from the tablet web preview, which mirrors the shipped app pixel for pixel. Written for onboarding a new teammate — pair it with a live walkthrough, not as a replacement for one.
